Jul 8, 1980

DOCUMENT-IDENTIFIER: US 4211880 A
TITLE: Resin-metal compound complex

Brief Summary Text (8):

Moore et al., in the Journal of the American Chemical Society, Vol. 72 (1950), pages 5792-3, disclose the adsorption of iron from a relatively concentrated hydrochloric acid solution on Dowex-1 by anion exchange.

Detailed Description Text (9):

The resin matrix of the weak base anion exchange resin contains chemically bonded thereto a basic, non-ionic functional group. The functional groups include primary, secondary, or tertiary amine groups. These may be aliphatic, aromatic, heterocyclic or cycloalkane amine groups. They may also be diamine, triamine, or alkanolamine groups. The amines may include alpha, alpha'-dipyridyl, guanidine, and dicyandiamidine groups. Other nitrogen-containing basic, non-ionic functional groups include nitrile, cyanate, isocyanate, thiocyanate, isothiocyanate, and isocyanide groups. Pyridine groups may also be employed.

Detailed Description Text (49):

Although low temperature liquid phase reactions are preferred, it will be appreciated that many low temperature reactions involve gaseous reactants and may be carried out in the gas phase, and the complexes can be applicable in these reactions. In some reactions, both liquid and gaseous reactants take part and are suitably catalyzed by the complexes. In all reactions, ease of catalyst separation by conventional operations of filtration, decantation, or centrifugation is a characteristic, whether the products and/or reactants are liquid or gaseous. The reactions may be carried out in conventional fixed bed flow reactors, or in continuously stirred flow reactors, or in batch reactors. Pressure may range to 300 atmospheres or more, and reaction times from less than one minute to several hours.

Detailed Description Text (69):

In place of KCl, other alkali metal halides, alkaline earth metal halides, especially the chlorides, and ammonium chloride, may be used.

Detailed Description Text (80):

The reaction mixture was heated to the reflux temperature to melt the sodium which was dispersed by the high speed stirrer. The resultant sodium dispersion was then cooled to room temperature and to it were added 10 ml. of a solution composed of 37.2 g. of chlorodiphenylphosphine dissolved in 50 ml. of para-dioxan. The resultant mixture was heated to the reflux temperature and 0.5 g. of naphthalene was added. The remainder of the chlorodiphenylphosphine solution was added to the reaction mixture dropwise over a period of three hours and the final reaction mixture was maintained at the reaction temperature for an additional 16 hours. The solution was cooled at 60.degree. C. and a 50 ml. aliquot of the reaction solution was withdrawn. To the remaining reaction mixture was added 50 g. of a solid resin, the resin being a copolymer of styrene and divinylbenzene which contained chloromethyl functional groups. On addition of the copolymer the reaction mixture temperature rose to 68.degree. C. Additional heat was applied to obtain reflux of the reaction mixture and this temperature was maintained for six hours. The

reaction mixture was then allowed to cool to room temperature and was allowed to stand overnight. The solids were then removed by filtration and washed consecutively with methanol, water, methanol, chloroform, benzene, and ether. The resin was then dried in a rotary evaporator at 50.degree. C. The yield of dry solids was 60.8 g. and they were found to have the following chemical analysis, on a weight basis: 3.86% of phosphorus, 13.4% of chlorine, 75.65% of carbon, and 6.19% of hydrogen.

Detailed Description Text (82):

A complex was prepared by dissolving 40 g. of nickel chloride hexahydrate, NiCl₂.2.6H₂O, in 1 liter (1.) of acetic acid and 1.5 l. of 1-butanol. The solution was heated to the reflux temperature and to this solution were added 20 g. of the phosphine resin of Example 9. The reaction mixture was stirred and maintained at the reflux temperature for 90 minutes. The complex was isolated by filtration, washed with 1-butanol, washed with methanol, washed with ether, and dried in a rotary evaporator. The yield of complex was 21.3 g. and had a chemical analysis, on a weight basis: 0.44% of Ni, 8.45% of Cl, 3.68% of P, 76.73% of C, and 7.53% of H.

Detailed Description Text (86):

A complex was prepared by dissolving 1.5 g. of bis-benzonitrile-palladium dichloride in 500 ml. of chloroform and adding to this solution about 20 g. of the phosphine resin of Example 9. The reaction mixture was heated to the reflux temperature for 1 hour at which time 50 ml. of benzonitrile were added and reflux maintained for an additional hour. The reaction mixture was then cooled to room temperature. The complex was isolated by filtration, washed with chloroform and dried in a rotary evaporator. The yield of complex was 21.9 g. and had a chemical analysis, on a weight basis: 1.53% of Pd, 11.2% of Cl, 3.9% of P, 70.02% of C, and 4.84% of H.

Detailed Description Text (90):

A complex was prepared by dissolving 1.15 g. of tris-triphenylphosphine-rhodium(I) chloride in 75 ml. of ethanol and adding to this solution 3.0 g. of the phosphine resin of Example 9. The mixture was heated to the reflux temperature for three hours and then cooled to room temperature. The complex was isolated by filtration, washed with ethanol, washed with ether, and dried at 110.degree. C.

Detailed Description Text (95):

The reaction mixture was stirred, heated to the reflux temperature for 5 hours and then cooled to room temperature. The complex was isolated by filtration, washed with water, washed with methanol, washed with ether, and dried. The yield of complex was 10.5 g. and had a chemical analysis, on a weight basis: 2.81% of Rh and 12.2% of S, and 0.93% of Cl.

Dec 28, 1999

DOCUMENT-IDENTIFIER: US 6008349 A

TITLE: Melamine polymetaphosphate and process for its production

Brief Summary Text (8):

It is known to employ urea as a condensing agent for the production of a polyphosphate. For example, JP-B-53-2170 discloses a process for producing an amide polyphosphate containing amide-type nitrogen, wherein a phosphoric acid source, such as ammonium orthophosphate, orthophosphoric acid, condensed phosphoric acid, phosphoric anhydride, urea phosphate or a mixture thereof, and a nitrogen source, such as melamine, a cyanamide derivative such as dicyan cyanamide, guanidine or guanyl urea, or a mixture thereof, are subjected to a heat condensation reaction in the presence of a condensing agent, such as urea, urea phosphate or a mixture thereof. With respect to the production conditions, it is disclosed that heat condensation is carried out at a molar ratio of urea/phosphoric acid (as H_{sub}3 PO_{sub}4)/cyanamide derivative=0.8 to 1.5/1/0.05 to 1 in an atmosphere of ammonia gas at a temperature of from 150 to 350.degree. C. for from 10 minutes to 5 hours, preferably from 1 to 4 hours. Example 1 of the same publication discloses that ammonium phosphate, industrial urea and melamine were mixed at a molar ratio of urea/phosphoric acid (as H_{sub}3 PO_{sub}4)/melamine=1/1/0.5 to obtain a material for calcination, which was subjected to heat condensation at a temperature of from 240 to 260.degree. C. for 2.5 hours to obtain a substantially water-insoluble amide polyphosphate (nitrogen: 33.48 wt %, diposphorus pentoxide: 44.73 wt %, elution ratio (10 g of a sample was put into 100 ml of water and stirred for 1 hour at a predetermined temperature, whereupon the elution ratio (%) was determined): 1.36%, pH of the 1% solution: 8.26).
